## Table of Contents

- **Introduction**
- **Chapter 1** Setting the Littoral: Geology, Monsoons, and the Bay of Bengal
- **Chapter 2** Before the City: Marshes, Backwaters, and the Pallikaranai Wetland
- **Chapter 3** Tanks and Channels: The Eris System and Precolonial Water Management
- **Chapter 4** Colonial Port and Canal: Buckingham Canal and the Making of a Maritime City
- **Chapter 5** Rivers Reconfigured: The Cooum and the Adyar through Time
- **Chapter 6** Salt Pans, Mangroves, and Mudflats: Coastal Ecologies at the Edge
- **Chapter 7** Fishing Communities and the Commons: From Catamarans to Mechanized Boats
- **Chapter 8** Sanitation and Sewage: Urban Health and the Politics of Wastewater
- **Chapter 9** Floods, Cyclones, and Storm Surges: Hazard, Memory, and Governance
- **Chapter 10** Mapping the Shoreline: Cartographies of Change, 17th–21st Centuries
- **Chapter 11** Reclamation and Real Estate: Filling Marshes, Raising Land
- **Chapter 12** Industrial North: Ports, Power, and Pollution at Ennore
- **Chapter 13** Sand, Stone, and Steel: Material Flows that Built Madras
- **Chapter 14** Water for a Thirsty Metropolis: Reservoirs, Wells, and Inter-basin Transfers
- **Chapter 15** The Canal in Decline and Renewal: Mobility, Drainage, and Heritage
- **Chapter 16** Green–Blue Infrastructure: Parks, Tanks, and Urban Biodiversity
- **Chapter 17** Informal Settlements and Environmental Justice: Who Bears the Risk?
- **Chapter 18** Law, Policy, and the Coast: CRZ, Wetland Rules, and Urban Regulation
- **Chapter 19** Science, Sensing, and Remote Imagery: Reading the City’s Environment
- **Chapter 20** Public Works and Politics: Institutions, Capacity, and Accountability
- **Chapter 21** Citizens, Courts, and Movements: Advocacy for Rivers and Wetlands
- **Chapter 22** Climate Change on the Coromandel: Sea-Level Rise, Heat, and Salinity
- **Chapter 23** Designing with Water: Planning for Floods, Droughts, and Everyday Rains
- **Chapter 24** Case Studies in Restoration: Pallikaranai, Adyar Creek, and Beyond
- **Chapter 25** Futures of the Littoral City: Scenarios, Trade-offs, and Ethics

## Introduction

Madras Environmental History: Coastlines, Canals, and Urban Ecology traces how a littoral landscape at the edge of the Bay of Bengal became a modern metropolis by channeling, dredging, draining, and reclaiming its waters. From marshes and backwaters to reclaimed land, the city's form has been continuously negotiated with monsoons, tides, and sediment. This book asks a simple question with complex answers: what happens when a city is built not only near water, but through it? The chapters that follow reconstruct the ecological past that underwrites present-day risks and possibilities, offering a long view for those grappling with floods, droughts, pollution, and coastal change.

Throughout the book I use "Madras" to evoke the *longue durée* of the region's environmental history while recognizing its contemporary identity as Chennai. This choice is not nostalgic; it is analytical. It allows us to read continuities across political regimes, languages, and planning paradigms that have all left their marks on land and water. By moving across time—from precolonial tank ecologies and early canal works to post-independence industrialization and twenty-first-century resilience planning—we see how yesterday's engineering fixes become today's vulnerabilities.

The city's environmental story begins with its coast. Barrier beaches, estuaries, and tidal creeks once braided a mosaic of mangroves, salt pans, and wetlands that buffered storms and stored seasonal rainfall. Two short rivers, the Cooum and the Adyar, carried monsoon pulses to the sea, while the Pallikaranai marsh moderated extremes and nurtured biodiversity. Living with this dynamism required social as much as technical skill: local communities stewarded tanks (*eris*), seasonal channels, and commons that spread water, silt, and benefit across the landscape. These practices formed an infrastructural culture attuned to variability, rather than against it.

Colonial expansion reoriented the shoreline and its waters to imperial commerce and urban growth. The Buckingham Canal stitched together lagoons and backwaters as a transport and drainage spine, while port works hardened a shifting coast. Revenue pressures and sanitary reform redrew the city's hydrology—reclaiming wetlands, straightening channels, and externalizing wastewater. Such interventions increased navigability and real estate in the short term, yet they also narrowed ecological margins, intensified flood peaks, and marginalized communities whose livelihoods depended on estuarine and coastal commons.

In the postcolonial decades, industrial corridors, housing schemes, and highway-led growth consolidated a metropolis that both depended on and distanced itself from its waters. New reservoirs, inter-basin transfers, and, later, desalination plants sought to

secure supply for a booming city, even as informal borewells, tanker markets, and encroachments proliferated. Northern neighborhoods near ports and power plants bore disproportionate pollution and hazard, while southern expansions pressed into marshlands and creek systems. Urban metabolism—of sand for concrete, coal for power, and land for infrastructure—reshaped coasts, canals, and riverbanks at unprecedented scales.

Contemporary Madras/Chennai faces the compound stresses of climate change, sea-level rise, heat, and saline intrusion layered atop historical modifications. Shoreline armoring, sand mining, and channelization attempt to hold a restless coast in place, often moving problems downstream or next door. Disasters—whether cyclonic floods or tsunamis—make visible the hidden infrastructures and decisions that accumulate into catastrophe. Yet the city also hosts experiments in restoration and governance: rejuvenated tanks, revived urban creeks, citizen science, litigation, and planning frameworks that seek to integrate green-blue networks with built form.

This book is written for environmental historians, urban ecologists, and planners seeking historical context for contemporary challenges. It combines archival research, historical cartography, remote sensing, oral histories, and policy analysis to show how ecological processes and political economies co-produce the city. Each chapter pairs narrative with evidence—maps, images, and data—to illuminate turning points: canalization and its aftermath, reclamation booms, sanitation campaigns, industrial siting, and the emergence of resilience as a planning idiom. Across these episodes runs a central lesson: designing with water—rather than despite it—requires memory.

Ultimately, Madras's environmental history is not only a chronicle of loss or risk; it is also a repertoire of practices for repair. By learning from tank ecologies, coastal commons, and community stewardship—while confronting the inequities embedded in past and present—we can imagine a more porous, just, and climate-ready city. The pages ahead offer neither a blueprint nor a lament, but a guide to reading the landscape so that future interventions respect its logics. In doing so, the book invites its readers to reimagine the metropolis as a living littoral system where ecology and urbanism are, and have always been, inseparable.

## **CHAPTER ONE: Setting the Littoral: Geology, Monsoons, and the Bay of Bengal**

The story of Madras, now Chennai, is inextricably linked to the restless rhythms of its coastal setting. Before any human settlement took root, before the first boat nudged its sandy shores, the very ground beneath the city was shaped by ancient geological forces and the relentless breath of the monsoons. To understand Madras's environmental history, we must first appreciate this dynamic stage - the interplay of its underlying geology, the powerful monsoon system, and the vast, often turbulent, Bay of Bengal.

The geology of the Tamil Nadu coast, where Madras proudly sits, is a fascinating patchwork. The deepest layers are formed from ancient crystalline rocks of the Archaean era, predominantly charnockite and khondalite groups, which account for over 80% of the state's landmass. These are the bedrock, the sturdy foundations upon which millennia of environmental change have unfolded. Overlying these ancient rocks are younger sedimentary deposits.

Along the coastal belt, including the Chennai region, these sedimentary rocks encompass fluvial, fluvio-marine, and marine sequences. These layers tell a story of rivers carrying sediment to the sea, of the sea encroaching and retreating, and of the constant deposition of materials that build up the land. The Cuddalore/Panambarai Formation, from the Mio-Pliocene epoch, and more recent Quaternary and Holocene sediments, including tidal flat deposits and coastal dunes, also characterize the region.

The coast itself is a testament to constant transformation, a delicate balance between erosion and deposition. Chennai's coast is notably characterized by high erosion in certain stretches, a dynamic process influenced by waves, tides, and cyclonic disturbances. However, it's not all loss; areas also experience accretion, with new land being formed. The diverse geomorphology includes sandy beaches, beach ridges, backwaters, mudflats, and paleo-tidal flats.

Speaking of sand, the beaches along the Tamil Nadu coast are not just for sunbathing. They hold significant deposits of heavy minerals like ilmenite and garnet, often appearing as black carpets due to their concentration. These mineral sands are a result of the longshore sediment transport, a continuous process where currents carry and deposit materials along the coastline, shaping and reshaping the very edge of the land.

But the real drama in this littoral setting is provided by the monsoons, the region's

dominant climate system. The Bay of Bengal plays a central role in this grand atmospheric dance. From November through April, a high-pressure system over the continent generates the northeast monsoon, bringing cooler, drier winds. However, as these winds travel over the Bay of Bengal, they pick up moisture and deliver much-needed rainfall to peninsular India, particularly the Madras coast, during October and December. In fact, 50% to 60% of Tamil Nadu's annual rainfall comes from this northeast monsoon.

Then comes the southwest monsoon, typically arriving between late May and early June and receding by late September or early October. This is the famous rain-bearing monsoon, fueled by intense heat over the Indian subcontinent that creates a low-pressure system, drawing moisture-laden air from the ocean. While the Arabian Sea branch of this monsoon brings heavy rains to India's west coast, the Bay of Bengal branch flows towards northeast India and Bengal, gathering more moisture along the way.

The Bay of Bengal is not just a passive recipient of these winds; it actively contributes to their intensity. A relatively warm area in the upper atmosphere over the southern Bay of Bengal, caused by the release of condensation heat from towering cumulonimbus clouds, helps to drive the monsoonal activity. This complex interaction ensures that the Bay is a dynamic force, not merely a backdrop, in shaping the region's climate.

However, the monsoons are not always a gentle bringer of life-giving rain. They are also responsible for some of the most destructive natural phenomena. Cyclones, intense tropical storms with high winds and torrential rains, are a recurring feature, especially during the transitional periods of April-May and October-November, before and after the main monsoon seasons. These powerful storms can cause significant damage, reminding us of the immense power of the Bay.

The Bay of Bengal itself is a massive basin, the largest in the world, and a major sink for sediments. Rivers, particularly the mighty Ganges-Brahmaputra system, transport vast quantities of eroded material from the Himalayas into the Bay. This continuous influx of sediment has a profound impact on the coastal environment, controlling coastal elevation and contributing to the formation of extensive deltas and shelves. The sedimentation rates vary throughout the year, with higher discharge during the summer monsoon.

This constant deposition and re-working of sediments, influenced by currents and waves, leads to a dynamic shoreline. The Bay's surface currents also change direction with the seasons, circulating clockwise during the northeast monsoon and counterclockwise during the southwest monsoon. These shifts play a crucial role in longshore sediment transport and the erosion and accretion patterns along the coast.

Over geological timescales, sea-level changes have significantly sculpted the Coromandel coast. During ice ages, when global ice sheets expanded, sea levels dropped, causing rivers to cut deeply into the land. As the ice sheets melted and sea levels rose, these river systems were drowned and often filled with mud and sand. This ongoing dance between land and sea has created the complex estuarine and backwater systems that characterize the Madras littoral.

The Chennai coast, in particular, exhibits a progradational nature generally, meaning it tends to build outwards due to sediment accumulation. This process has led to the formation of large lagoons and wetlands, crucial ecosystems that we will explore in later chapters. However, this progradation is not uniform, with some stretches experiencing erosion, highlighting the constant flux of the coastal environment.

Therefore, the stage for Madras's environmental history is set by a foundation of ancient rocks, overlain by diverse sedimentary layers, constantly reshaped by the powerful forces of the Bay of Bengal and the rhythmic, yet sometimes violent, dance of the monsoons. This intricate interplay of geology and climate has created a coastline of both stability and flux, a landscape that has always demanded a keen awareness of its natural rhythms from those who chose to inhabit it. The city's very existence, its vulnerabilities, and its opportunities are all rooted in this dynamic littoral environment.
